SVM

- Said to start in 1979 with Vladimir Vapnik's paper

- Major developments throughout 1990's

- Elegant theory
  - Has good generalization properties

- Have been applied to diverse problems very successfully in the last 10-15 years

- One of the most important developments in pattern recognition in the last 10 years

Problem Definition

Consider a training set of n iid samples

$$(x_1, y_1), (x_2, y_2), ..., (x_n, y_n)$$

where x_i is a vector of length m and

$y_i \in \{+1, -1\}$ is the class label for data point x_i.

Find a separating hyperplane $w \cdot x + b = 0$

corresponding to the decision function
$$f(x) = sign(w \cdot x + b)$$

Separating Hyperplanes

- which separating hyperplane should we choose?

Separating Hyperplanes

- Training data is just a subset of of all possible data
- Suppose hyperplane is close to sample x_i
- If we see new sample close to sample i, it is likely to be on the wrong side of the hyperplane

- Poor generalization (performance on unseen data)
Separating Hyperplanes

- Hyperplane as far as possible from any sample
- New samples close to the old samples will be classified correctly
- Good generalization

SVM

- Idea: maximize distance to the closest example

smaller distance

larger distance

- For the optimal hyperplane
 - distance to the closest negative example = distance to the closest positive example

SVM: Linearly Separable Case

- SVM: maximize the *margin*

- *margin* is twice the absolute value of distance *d* of the closest example to the separating hyperplane
- Better generalization (performance on test data)
  - in practice
  - and in theory

# SVM: Linearly Separable Case

- **Support vectors** are the samples closest to the separating hyperplane
    - they are the most difficult patterns to classify
    - Optimal hyperplane is completely defined by support vectors
        - of course, we do not know which samples are support vectors without finding the optimal hyperplane

SVM: Formula for the Margin

- $g(x) = w^t x + b$

- absolute distance between x and the boundary $g(x) = 0$

$$\frac{\left| w^t x + b \right|}{\| w \|}$$
- distance is unchanged for hyperplane $g_1(x) = \alpha g(x)$

$$\frac{\left| \alpha\, w^t x + \alpha\, b \right|}{\| \alpha\, w \|} = \frac{\left| w^t x + b \right|}{\| w \|}$$

- Let x_i be an example closest to the boundary. Set

$$\left| w^t x_i + b \right| = 1$$

- Now the largest margin hyperplane is unique

# *SVM: Formula for the Margin*

- For uniqueness, set $\left| \mathbf{w}^t \mathbf{x}_i + b \right| = 1$ for any example $\mathbf{x}_i$ closest to the boundary

- now distance from closest sample $\mathbf{x}_i$ to $g(\mathbf{x}) = \mathbf{0}$ is

$$\frac{\left| \mathbf{w}^t \mathbf{x}_i + b \right|}{\|\mathbf{w}\|} = \frac{1}{\|\mathbf{w}\|}$$

- Thus the margin is

$$m = \frac{2}{\|\mathbf{w}\|}$$

SVM: Optimal Hyperplane

- Maximize margin $m = \dfrac{2}{\|\mathbf{w}\|}$

  subject to constraints

$$\begin{cases} \mathbf{w}^{t}\mathbf{x}_{i} + \boldsymbol{b} \geq \mathbf{1} & \mathbf{y}_{i} = \mathbf{1} \\ \mathbf{w}^{t}\mathbf{x}_{i} + \boldsymbol{b} \leq -\mathbf{1} & \mathbf{y}_{i} = \textbf{-1} \end{cases}$$

- Can convert our problem to

$$J(\mathbf{w}) = \frac{1}{2}\|\mathbf{w}\|^{2} \qquad \text{s.t} \quad y_{i}(\mathbf{w} \cdot \mathbf{x}_{i} + \boldsymbol{b}) \geq \mathbf{1}$$

- $J(\boldsymbol{w})$ is a quadratic function, thus there is a single global minimum

Constrained Quadratic Programming

Primal Problem:

Minimize $\dfrac{1}{2}\|\mathbf{w}\|^2$

subject to $y_i(\mathbf{w}\cdot\mathbf{x}_i + b) \geq 1,\ \forall i$

- Introduce Lagrange multipliers $\alpha_i \geq 0$ associated with the constraints

- The solution to the primal problem is equivalent to determining the saddle point of the function

$$L_P \equiv L(\mathbf{w}, b, \alpha) = \frac{1}{2}\|\mathbf{w}\|^2 - \sum_{i=1}^{n}\alpha_i\left(y_i(\mathbf{x}_i\cdot\mathbf{w} + b) - 1\right)$$

Solving Constrained QP

- At saddle point, L_P has minimum requiring

$$\frac{\partial L_P}{\partial \mathbf{w}} = \mathbf{w} - \sum_i \alpha_i y_i \mathbf{x}_i = \mathbf{0} \implies \mathbf{w} = \sum_i \alpha_i y_i \mathbf{x}_i$$

$$\frac{\partial L_P}{\partial b} = \sum_i \alpha_i y_i = \mathbf{0}$$

Primal-Dual

Primal:

$$L_P = \frac{1}{2}\|\mathbf{w}\|^2 - \sum_{i=1}^{n} \alpha_i y_i (\mathbf{x}_i \cdot \mathbf{w} + b) + \sum_{i=1}^{n} \alpha_i$$

minimize L_P with respect to w,b,
subject to $\alpha_i \geq 0$

$$\mathbf{w} = \sum_i \alpha_i y_i \mathbf{x}_i \qquad \sum_i \alpha_i y_i = 0 \qquad \text{substitute}$$

Dual:

$$L_D = \sum_{i=1}^{l} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_j y_i y_j \mathbf{x}_i \mathbf{x}_j$$

maximize L_D with respect to $\boldsymbol{\alpha}$
subject to $\alpha_i \geq 0, \qquad \sum_i \alpha_i y_i = 0$

Solving QP using dual problem

$$\text{maximize} \quad L_D(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j y_i y_j \mathbf{x}_i^t \mathbf{x}_j$$

$$\text{constrained to} \quad \alpha_i \geq 0 \quad \forall i \quad and \quad \sum_{i=1}^{n} \alpha_i y_i = 0$$

- $\alpha = \{\alpha_1, \ldots, \alpha_n\}$ are new variables, one for each sample

- $L_D(\alpha)$ can be optimized by quadratic programming

- $L_D(\alpha)$ formulated in terms of α
  - it depends on **w** and **b** indirectly

Threshold

- **b** can be determined from the optimal α and Karush-Kuhn-Tucker (KKT) conditions

$$\alpha_i \left[y_i \left(\mathbf{w} \cdot \mathbf{x}_i + b \right) - 1 \right] = 0, \quad \forall i$$

- $\alpha_i > 0$ implies

$$y_i \left(\mathbf{w} \cdot \mathbf{x}_i + b \right) = 1 \quad \Rightarrow \quad \mathbf{w} \cdot \mathbf{x}_i + b = y_i$$

$$b = y_i - \mathbf{w} \cdot \mathbf{x}_i$$

Support Vectors

- For every sample *i*, one of the following must hold
  - $\alpha_i = 0$
  - $\alpha_i > 0$ and $y_i(w \cdot x_i + b - 1) = 0$

- Many $\alpha_i = 0 \Rightarrow w = \sum_i \alpha_i y_i x_i$ sparse solution

- Samples with $\alpha_i > 0$ are *Support Vectors* and they are the closest to the separating hyperplane

- Optimal hyperplane is completely defined by support vectors

More on dual problem

$$L_D(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j y_i y_j x_i^t x_j$$

maximize

constrained to $\quad \alpha_i \geq 0 \quad \forall i \quad and \quad \sum_{i=1}^{n} \alpha_i y_i = 0$

- $L_D(\alpha)$ depends on the number of samples, not on dimension of samples
- samples appear only through the dot products $x_i^t x_j$
- This will become important when looking for a **nonlinear** discriminant function, as we will see soon

SVM: Classification

- Given a new sample x, finds its label y
$$y = sign(\mathbf{w} \cdot \mathbf{x} + b)$$
$$\mathbf{w} = \sum_{i=1}^{n} \alpha_i y_i x_i \qquad \text{duality}$$

$$y = sign(\sum_{i=1}^{n} \alpha_i y_i \mathbf{x_i} \cdot \mathbf{x} + b)$$

SVM: Example
- Class 1: [1,6], [1,10], [4,11]
- Class 2: [5,2], [7,6], [10,4]

SVM: Example

- Solution $\alpha = \begin{bmatrix} \mathbf{0.036} \\ \mathbf{0} \\ \mathbf{0.039} \\ \mathbf{0} \\ \mathbf{0.076} \\ \mathbf{0} \end{bmatrix}$ *support vectors*

- find w using $w = \sum_{i=1}^{n} \alpha_i y_i x_i = (\alpha .* y)^t x = \begin{bmatrix} -\mathbf{0.33} \\ \mathbf{0.20} \end{bmatrix}$

- since $\alpha_1 > 0$, can find b using

$$b = \frac{1}{y_1} - w^t x_1 = \mathbf{0.13}$$

SVM: Non Separable Case

- Data is most likely to be not linearly separable, but linear classifier may still be appropriate

- Can apply SVM in non linearly separable case
  - data should be "almost" linearly separable for good performance

SVM with slacks

- Use nonnegative "slack" variables $\xi_1,\ldots,\xi_n$ (one for each sample)

- Change constraints from $y_i\left(\mathbf{w}^t\mathbf{x}_i + b\right) \geq 1 \quad \forall i$ to

$$y_i\left(\mathbf{w}^t\mathbf{x}_i + b\right) \geq 1 - \xi_i \quad \forall i$$

- ξ_i is a measure of deviation from the ideal for sample i

  - $\xi_i > 1$ sample i is on the wrong side of the separating hyperplane
  - $0 < \xi_i < 1$ sample i is on the right side of separating hyperplane but within the region of maximum margin
SVM with slacks

- Would like to minimize

$$J(w, \xi_1, \ldots, \xi_n) = \frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n}\xi_i$$

  - constrained to $y_i(\mathbf{w}^t\mathbf{x}_i + b) \geq 1 - \xi_i$ and $\xi_i \geq 0 \quad \forall i$

  - $C > 0$ is a constant which measures relative weight of the first and second terms
    - if C is small, we allow a lot of samples not in ideal position
    - if C is large, we want to have very few samples not in ideal position

SVM with slacks

$$J\left(w, \xi_1, \ldots, \xi_n\right) = \frac{1}{2}\|w\|^2 + C \sum_{i=1}^{n} \xi_i$$

large C, few samples not in ideal position

small C, a lot of samples not in ideal position

SVM with slacks– Dual Formulation

maximize $\quad L_D(\alpha) = \sum\limits_{i=1}^{n} \alpha_i - \dfrac{1}{2} \sum\limits_{i=1}^{n} \sum\limits_{j=1}^{n} \alpha_i \alpha_i y_i y_j x_i^t x_j$

constrained to $\quad 0 \le \alpha_i \le C \quad \forall i \quad and \quad \sum\limits_{i=1}^{n} \alpha_i y_i = 0$

- find **w** using $\quad w = \sum\limits_{i=1}^{n} \alpha_i y_i x_i$

- solve for **b** using any $0 < \alpha_i < C$ and $\alpha_i [y_i (\mathbf{w}^t \mathbf{x}_i + b) - 1] = 0$
Non Linear Mapping

- Cover's theorem:
  - "*pattern-classification problem cast in a high dimensional space non-linearly is more likely to be linearly separable than in a low-dimensional space*"

- One dimensional space, not linearly separable
- Lift to two dimensional space with $\varphi(x)=(x, x^2)$

Non Linear Mapping

- To solve a non linear classification problem with a linear classifier
  1. Project data x to high dimension using function $\varphi(x)$
  2. Find a linear discriminant function for transformed data $\varphi(x)$
  3. Final nonlinear discriminant function is $g(x) = w^t \varphi(x) + w_0$

$$\varphi(x) = (x, x^2)$$

-3 -2   0   1   2   3   5

R_2 R_1 R_2
- In 2D, discriminant function is linear

$$g\left(\begin{bmatrix} x^{(1)} \\ x^{(2)} \end{bmatrix}\right) = \begin{bmatrix} w_1 & w_2 \end{bmatrix} \begin{bmatrix} x^{(1)} \\ x^{(2)} \end{bmatrix} + w_0$$

- In 1D, discriminant function is not linear $\quad g(x) = w_1 x + w_2 x^2 + w_0$

Non Linear Mapping: Another Example
Non Linear SVM

- Can use any linear classifier after lifting data into a higher dimensional space. However we will have to deal with the "curse of dimensionality"
  1. poor generalization to test data
  2. computationally expensive

- SVM avoids the "curse of dimensionality" problems by
  1. enforcing largest margin permits good generalization
     - It can be shown that generalization in SVM is a function of the margin, independent of the dimensionality
  2. computation in the higher dimensional case is performed only implicitly through the use of *kernel* functions

Non Linear SVM: Kernels

- Recall SVM optimization

  maximize $L_D(\alpha) = \sum\limits_{i=1}^{n} \alpha_i - \dfrac{1}{2}\sum\limits_{i=1}^{n}\sum\limits_{j=1}^{n} \alpha_i\alpha_i y_i y_j x_i^t x_j$

- Note this optimization depends on samples x_i only through the dot product $x_i^t x_j$

- If we lift x_i to high dimensional space F using $\varphi(x)$, need to compute high dimensional product $\varphi(x_i)^t\varphi(x_j)$

  maximize $L_D(\alpha) = \sum\limits_{i=1}^{n} \alpha_i - \dfrac{1}{2}\sum\limits_{i=1}^{n}\sum\limits_{j=1}^{n} \alpha_i\alpha_i y_i y_j \varphi(x_i)^t\varphi(x_j)$

- The dimensionality of space F not necessarily important. May not even know the map φ.

Kernel

- A function that returns the value of the dot product between the images of the two arguments:

$$K(\text{x,y}) = \varphi(\boldsymbol{x}_i)^t \varphi(\boldsymbol{x}_j)$$

- Given a function K, it is possible to verify that it is a kernel.

$$\text{maximize } L_D(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_i y_i y_j \underbrace{\varphi(\boldsymbol{x}_i)^t \varphi(\boldsymbol{x}_j)}_{K(\boldsymbol{x}_i, \boldsymbol{x}_j)}$$

- Now we only need to compute $\boldsymbol{K}(\boldsymbol{x}_i, \boldsymbol{x}_j)$ instead of $\varphi(\boldsymbol{x}_i)^t \varphi(\boldsymbol{x}_j)$

    - "kernel trick": do not need to perform operations in high dimensional space explicitly

Kernel Matrix

- (aka the Gram matrix):

$$
K=
\begin{array}{|c|c|c|c|c|}
\hline
K(1,1) & K(1,2) & K(1,3) & \dots & K(1,m) \\
\hline
K(2,1) & K(2,2) & K(2,3) & \dots & K(2,m) \\
\hline
 & & & & \\
\hline
\dots & \dots & \dots & \dots & \dots \\
\hline
K(m,1) & K(m,2) & K(m,3) & \dots & K(m,m) \\
\hline
\end{array}
$$

- The central structure in kernel machines
- Contains all necessary information for the learning algorithm
- Fuses information about the data AND the kernel
- Many interesting properties:

From www.support-vector.net

Mercer's Theorem

- The kernel matrix is Symmetric Positive Definite

- Any symmetric positive definite matrix can be regarded as a kernel matrix, that is as an inner product matrix in some space

Every (semi)positive definite, symmetric
function is a kernel: i.e. there exists a mapping φ such that it is possible to write:

$$K(x,y) = \varphi(x)^t \varphi(y)$$

Positive definite $\displaystyle\int_{\forall f \in L_2} K(x,y) f(x) f(y) \, dxdy \geq 0$

From www.support-vector.net

Examples of Kernels

- Some common choices (both satisfying Mercer's condition):

  - Polynomial kernel $K(x_i, x_j) = (x_i^t x_j + 1)^p$

  - Gaussian radial Basis kernel (data is lifted in infinite dimension)

$$K(x_i, x_j) = \exp\left(-\frac{1}{2\sigma^2}\|x_i - x_j\|^2\right)$$

From www.support-vector.net

Example: Polynomial Kernels

$$x = (x_1, x_2);$$

$$z = (z_1, z_2);$$

$$K(x,z) \equiv \langle x,z \rangle^2 = (x_1 z_1 + x_2 z_2)^2 =$$

$$x_1^2 z_1^2 + x_2^2 z_2^2 + 2 x_1 z_1 x_2 z_2 =$$

$$\left\langle (x_1^2, x_2^2, \sqrt{2} x_1 x_2), (z_1^2, z_2^2, \sqrt{2} z_1 z_2) \right\rangle =$$

$$\langle \phi(x), \phi(z) \rangle$$
From www.support-vector.net

Example Polynomial Kernels

From www.support-vector.net

Example: the two spirals

- Separated by a hyperplane in feature space (gaussian kernels)

From www.support-vector.net

Making Kernels

- The set of kernels is closed under some operations. If K, K' are kernels, then:

- K+K' is a kernel

- cK is a kernel, if c>0

- aK+bK' is a kernel, for a,b >0

- Etc etc etc……

- can make complex kernels from simple ones: modularity !

Non Linear SVM Recepie

- Start with data $x_1,\dots,x_n$ which lives in feature space of dimension d

- Choose kernel $K(x_i,x_j)$ corresponding to some function $\varphi(x_i)$ which takes sample x_i to a higher dimensional space

- Find the largest margin linear discriminant function in the higher dimensional space by using quadratic programming package to solve:

$$\text{maximize} \quad L_D(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_i y_i y_j K(x_i, x_j)$$

$$\text{constrained to} \quad 0 \le \alpha_i \le C \quad \forall i \quad \text{and} \quad \sum_{i=1}^{n} \alpha_i y_i = 0$$

Non Linear SVM Recipe

- Weight vector w in the high dimensional space:

$$w = \sum_{i}^{n} \alpha_i y_i \varphi(x_i)$$

- Linear discriminant function of largest margin in the high dimensional space:

$$g(\varphi(x)) = w^t \varphi(x) = \left(\sum_{x_i \in S} \alpha_i y_i \varphi(x_i) \right)^t \varphi(x)$$

- Non linear discriminant function in the original space:

$$g(x) = \left(\sum_{x_i \in S} \alpha_i y_i \varphi(x_i) \right)^t \varphi(x) = \sum_{x_i \in S} \alpha_i y_i \varphi^t(x_i) \varphi(x) = \sum_{x_i \in S} \alpha_i y_i K(x_i, x)$$

- decide class 1 if $g(x) > 0$, otherwise decide class 2

Non Linear SVM

- Nonlinear discriminant function

$$g(x) = \sum_{x_i \in S} \boxed{\alpha_i} \boxed{z_i} \boxed{K(x_i, x)}$$

$$g(x) = \sum$$

most important
training samples,
i.e. support vectors

| weight of support vector x_i | $\boxed{\mp 1}$ | "inverse distance" from x to support vector x_i |

$$K(x_i, x) = \exp\left(-\frac{1}{2\sigma^2}\|x_i - x\|^2\right)$$

Toy Example with a Gaussian Kernel

Higher Order Polynomials
Taken from Andrew Moore

Poly-nomial	$\phi(x)$	Cost to build H matrix traditionally	Cost if d=100	$\phi(a)^t\phi(b)$	Cost to build H matrix sneakily	Cost if d=100
Quadratic	All $d^2/2$ terms up to degree 2	$d^2 n^2 /4$	$2{,}500\ n^2$	$(a^t b + 1)^2$	$d\,n^2/2$	$50\ n^2$
Cubic	All $d^3/6$ terms up to degree 3	$d^3 n^2 /12$	$83{,}000\ n^2$	$(a^t b + 1)^3$	$d\,n^2/2$	$50\ n^2$
Quartic	All $d^4/24$ terms up to degree 4	$d^4 n^2 /48$	$1{,}960{,}000\ n^2$	$(a^t b + 1)^4$	$d\,n^2/2$	$50\ n^2$

n is the number of samples, d is number of features

SVM Example: XOR Problem

- Class 1: $x_1 = [1,-1]$, $x_2 = [-1,1]$

- Class 2: $x_3 = [1,1]$, $x_4 = [-1,-1]$

- Use polynomial kernel of degree 2:
  - $K(x_i, x_j) = (x_i^t x_j + 1)^2$
  - This kernel corresponds to mapping

$$\varphi(x) = \left[1 \quad \sqrt{2}x^{(1)} \quad \sqrt{2}x^{(2)} \quad \sqrt{2}x^{(1)}x^{(2)} \quad \left(x^{(1)}\right)^2 \quad \left(x^{(2)}\right)^2 \right]^t$$

- Need to maximize

$$L_D(\alpha) = \sum_{i=1}^{4} \alpha_i - \frac{1}{2} \sum_{i=1}^{4} \sum_{j=1}^{4} \alpha_i \alpha_i z_i z_j \left(x_i^t x_j + 1\right)^2$$

constrained to $\quad 0 \leq \alpha_i \quad \forall i \quad$ and $\quad \alpha_1 + \alpha_2 - \alpha_3 - \alpha_4 = 0$
SVM Example: XOR Problem

- Can rewrite $L_D(\alpha) = \sum_{i=1}^{4} \alpha_i - \dfrac{1}{2}\alpha^t H \alpha$

  - $H_{ij} = z_i z_j K(x_i, x_j)$ where $K(x_i, x_j) = (x_i^t x_j + 1)^2$

  - Thus $H = \begin{bmatrix} 9 & 1 & -1 & -1 \\ 1 & 9 & -1 & -1 \\ -1 & -1 & 9 & 1 \\ -1 & -1 & 1 & 9 \end{bmatrix}$

- Take derivative with respect to α and set it to **0**

$$\dfrac{d}{da} L_D(\alpha) = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} - \begin{bmatrix} 9 & 1 & -1 & -1 \\ 1 & 9 & -1 & -1 \\ -1 & -1 & 9 & 1 \\ -1 & -1 & 1 & 9 \end{bmatrix} \alpha = 0$$

- Solution to the above is $\alpha_1 = \alpha_2 = \alpha_3 = \alpha_4 = $ **0.25**

  - satisfies the constraints $\forall i,\ 0 \le \alpha_i$ **and** $\alpha_1 + \alpha_2 - \alpha_3 - \alpha_4 = 0$

  - all samples are support vectors

SVM Example: XOR Problem

$$\varphi(x) = \begin{bmatrix} 1 & \sqrt{2}\,x^{(1)} & \sqrt{2}\,x^{(2)} & \sqrt{2}\,x^{(1)}x^{(2)} & \left(x^{(1)}\right)^2 & \left(x^{(2)}\right)^2 \end{bmatrix}^t$$

- Class 1: $x_1 = [1,-1]$, $x_2 = [-1,1]$
- Class 2: $x_3 = [1,1]$, $x_4 = [-1,-1]$

- Weight vector w is:

$$w = \sum_{i=1}^{4} \alpha_i z_i \varphi(x_i) = 0.25\left(\varphi(x_1) + \varphi(x_2) - \varphi(x_3) - \varphi(x_4)\right)$$

$$= \begin{bmatrix} 0 & 0 & 0 & -\sqrt{2} & 0 & 0 \end{bmatrix}$$

- Thus the nonlinear discriminant function is:

$$g(x) = w\varphi(x) = \sum_{i=1}^{6} w_i \varphi_i(x) = -\sqrt{2}\left(\sqrt{2}\,x^{(1)}x^{(2)}\right) = -2\,x^{(1)}x^{(2)}$$

SVM Example: XOR Problem

$$g(x) = -2x^{(1)}x^{(2)}$$
decision boundaries nonlinear

decision boundary is linear

SVM Summary

- Advantages:
  - Based on nice theory
  - excellent generalization properties
  - objective function has no local minima
  - can be used to find non linear discriminant functions
  - Complexity of the classifier is characterized by the number of support vectors rather than the dimensionality of the transformed space

- Disadvantages:
  - It's not clear how to select a kernel function in a principled manner
  - tends to be slower than other methods
